Acoustic Fatigue Analysis Of Weld

The nominal stress method is a relatively simple and inexpensive method to compute the fatigue life in a weld, and it is quite well adapted for using COMSOL Multiphysics to obtain the loads and stress distribution. Effective Notch Stress Method. Another method to compute the fatigue life of a welded joint is to analyze the final geometry of the weld.

High acoustic energy has the potential to cause vibration induced fatigue in a piping system at integral attachments such as welded pipe supports. Although recognized as a potential failure location, there is no established design curve and fatigue life equation among industry guidelines. In this paper, acoustic induced vibration (AIV) at welded supports is evaluated using Finite Element Analysis.

Abstract Weld seams are critical points for the initiation of fatigue cracks in steel structures subjected to cyclic loads. Semi-elliptical surface cracking at the toes of a fillet weld is not easily found when it is partially through the thickness and subcritical.

Analysis Methods for Fatigue of Welds

Joint weld diameters were measured using scanning acoustic microscopy. Fatigue tests were performed to obtain the fatigue lives of two joint types subjected to different stress levels. The equations of load-life curves were obtained by nonlinear regression using a three parameter power function.

SwRI Method Overview •Valve excitation analysis, acoustic analysis and finite element analysis performed to determine coincidence of acoustic and pipe shell modes •Forced response analysis of FE model at coincident modes performed with shell models to determine stresses at fillet weld and resulting fatigue life.

An FEA-Based Acoustic Fatigue Analysis Methodology

apply traditional methods of fatigue analysis to welds, an appropriate value of the stress concentration factor and residual stress must be selected. Although the smallest radius produces the largest stress concentration factor, its effect in fatigue is smaller because of the gradient effect. As

Acoustic Fatigue High noise at pressure reducing devices, such as pressure relief valves or restriction orifices, excites downstream piping, induces piping vibration and leads to high stress at the branch or welding support. Acoustic fatigue is a phenomenon that causes damage to piping by high stress due to high noise.

Acoustic Analysis Technologies and Acoustic Fatigue ...

Fatigue crack propagation data for each weld wire is of interest because of its use for predicting and analyzing service failures. Fatigue crack growth test specimens were developed and fabricated for the low carbon steel base metal and for each weld wire. Weld specimens were stress relieved prior to fatigue testing.

Analysis of Fatigue Crack Propagation In Welded Steels

Most fatigue design rules present a series of S-N curves for particular weld details (Fig.2), where S is the nominal stress range adjacent to the weld detail. These are derived from constant amplitude fatigue test data, obtained from welded specimens, by statistical analysis.

A fatigue enhancement factor f(R) may be considered by increasing the fatigue class if the residual stresses are known. This enhancement is dependant on the stress ratio, R, and the type of weld. If no reliable information on residual stress is available, an enhancement factor f(R) = 1 is recommended.

normal to the weld toe line is the largest in magnitude and it is predominantly responsible for the fatigue damage accumulation in this region. Therefore, it is suffi cient in practice to consider for the fatigue analysis of welded joints only the stress component, i.e. its magnitude and distribution across the plate thickness.
