Biology for Kids: The Skin

The skin is composed of two major layers: a superficial epidermis and a deeper dermis. The epidermis consists of several layers. The topmost layer consists of dead cells that shed periodically and is progressively replaced by cells formed from the basal layer.

Basic Biology of the Skin - Jones & Bartlett Learning Functions of the skin The skin is multipurpose, meaning it has a lot of functions. It's our first line of protection against the outside environment, it houses one of our five senses, it absorbs sunlight for vitamin D and heat, and regulates our internal temperature.

With intrinsic ageing, skin becomes thin, smooth, finely wrinkled and more transparent whereas photoaged skin is thickened, sallow and yellow and coarsely wrinkled. Throughout adult life the collagen content of the skin declines by roughly 1% per year. Sagging occurs because of disintegration of elastin fibres.

The Biology of the Skin

The skin has two main layers, the epidermis and dermis. Below these is a layer of subcutaneous ('under the skin') fat. The epidermis. The outer surface of the skin is the epidermis, which itself contains several layers — the basal cell layer, the spinous cell layer, the granular cell layer, and the stratum corneum.

The largest organ of your body is your skin (known as integument in the world of clinical anatomy). It includes the outer covering that protects your inside parts from the elements and from viruses and bacteria. The skin is also necessary for heat regulation, sensation, and making vitamin D. The skin can be a good indicator of health.

Three Basic Cell Types in the Epidermis The three basic cell types in the epidermis include keratinocytes (some labeled K) and Langerhans cells (L) in the Malpighian layer and melanocytes (M) in the basal layer. Arrows point to the basement membrane zone, which separates the basal layer of the epidermis from the underlying dermis (D).

A primary reason for this perspective is to highlight the utility of in vivo model systems, and specifically the skin, in studies of basic cell biological regulators. For basic cell biologists looking for in vivo systems to expand into, the skin offers a combination of advantages that other tissues do not possess.

Collagen is the major structural component of the dermis and is the tissue that is most responsible for the youthful appearance of our skin. Skin consists of 75% collagen, which in turn accounts for up to 90% of the connective tissues (dermis). Collagen is capable of retaining as much as 8 times its weight in water.

The dermis is the thick, elastic but firm middle layer of the skin, beneath the epidermis. This skin layer's main structural components are collagen, elastin, and connective tissues. These provide strength and flexibility and are vital components of healthy, young-looking skin. The dermis is made up of 2 sub-layers:
