Chapter 3 Diodes Problem Solutions

4 CHAPTER 3. DIODES, PROBLEM SOLUTIONS At $V = 0.1 \text{ V}$, I_D is: $I_D = I_{se} 0.1/0.25 = I_{se} 4 = I_s \times 54.6$ $I_D I_s = 54.6$ The reverse leakage current doubles for every 10 C rise, so for a 50 C rise the current increases by a factor of 25. I_S doubles for every 5 C rise, so for a 50 C rise I_s increases by a factor of 210. we then have: $I_D = I_s e^{V/V_T} 25 \times I_D = 2 \times 10 \times I_{se} V/V_T V = V$

, of diodes assumed to ON and the voltages, v_D , of the diodes assume to be OFF 3. Check to see if i_D is positive for all diodes assumed to be ON and v_D is negative for all diodes assumed to be OFF 4. If this is true, then the solution is complete; otherwise return to step 1 by assuming a different set of states for the diodes.

matches that of the arrow in the diode symbol, and $V_D \geq 0.7V$ for silicon, $V_D \geq 0.3V$ for germanium, and $V_D \geq 1.2V$ for gallium arsenide. You may assume the diode is "on", and then find the current in the diode. If the current flows into the positive terminal of the diode, then the assumption is right, otherwise, the diode is "off".

How to Solve the Diode Circuits (Explained with Examples)

* A diode may be thought of as an electrical counterpart of a directional valve ("check valve"). * A check valve presents a small resistance if the pressure $p > 0$, but blocks the flow (i.e., presents a large resistance) if $p < 0$. * Similarly, a diode presents a small resistance in the forward direction and a large resistance in the reverse direction.

To try solve this problem i used the technique, "assumed states for analysis of ideal switch model diode circuits" (not sure if thats the actual name of the technique). So for my first state, i assumed that both D1 and D2 are on Since the current are not negative for both diodes, the assumption for both diodes being on must be correct.
