An anechoic chamber (an-echoic meaning "non-reflective, non-echoing, echo-free") is a room designed to completely absorb reflections of either sound or electromagnetic waves.They are also often isolated from waves entering from their surroundings. This combination means that a person or detector exclusively hears direct sounds (no reverberant sounds), in effect simulating being inside an ...

A large anechoic chamber (cut-off frequency of 50 Hz, structure-born vibration of 3 Hz) is used for the development of acoustic measuring techniques. Flow noise phenomena, e.g. noise generated at turbine blades, are investigated in an extremely laminar and noiseless wind tunnel (50 m/s). Noise abatement is carried out with "acoustic material".

However, little is known about the acoustic sense of sea otters, including sensitivity to airborne and underwater sound. In this study, we sought to obtain direct measures of auditory function. We trained an adult-male southern sea otter to participate in audiometric testing in an acoustic chamber and an acoustically mapped pool.

All three sound chambers can be used for behavioral and psychophysical experiments in which quiet conditions and precise control over acoustic conditions are required. Each chamber is equipped with...

A precision-grade free-field environment is a product of the anechoic chamber's sound absorption system that consists of melamine wedges installed on a patented clip system that provides fast wedge installation and removal. Unlike other wedge solutions, melamine wedges provide a bright and fiber-free working environment.

This work uses psychophysical measures of function to directly test the hypothesis that there is an auditory percept associated with electromotile hearing, and further, that the percept is a tonal acoustic sensation.

- model assumes that an acoustic signal enters the auditory system causing behavior that we record as psychophysical observations - psychophysical methods and sound perception experiments determine how the brain processes signals with different loudness levels, different spectral characteristics, and different temporal properties

Psychoacoustics: A Brief Historical Overview

An Introduction to Acoustics S.W. Rienstra & A. Hirschberg Eindhoven University of Technology 28 Nov 2019 This is an extended and revised edition of IWDE 92-06.

An Introduction to Acoustics

The current psychophysical experiments support the hypothesis that human subjects can exploit auditory motion parallax to discriminate distances of sound sources. Thus, the capacity to exploit motion parallax to disambiguate sensory scenes is shared between the senses of vision and audition.

Psychophysical Evidence of Tinnitus and Cochlear Damage The suppression ratio (R) is a relative measure of what an animal hears when tested with acoustic stimuli. This measure can be interpreted as a reflection of tinnitus because a test tone that is qualitatively similar to an animal's tinnitus will be heard differently in an animal with tinnitus compared to an animal without tinnitus.

Two chapters are comparative lab-based studies that utilized psychophysical approaches conducted in an acoustic chamber. Chapter 1 addressed the frequency-dependent sound localization abilities at azimuth of three pinniped species (the harbor seal, Phoca vitulina, the California sea lion, Zalophus californianus, and the northern elephant seal, Mirounga angustirostris).
